     Q3. Call the summary() function on your results to get a sense of how many genes
     are up or down-regulated at the default 0.1 p-value cutoff.

Q4. Improve this plot by completing the below code, which adds color and axis labels

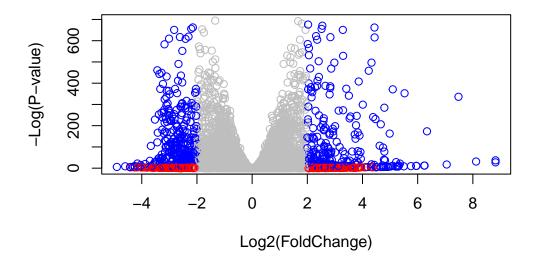

Make a color vector for all genes

```
mycols <- rep("gray", nrow(res))

# Color red the genes with absolute fold change above 2
mycols[ abs(res$log2FoldChange) > 2 ] <- "red"

# Color blue those with adjusted p-value less than 0.01
# and absolute fold change more than 2
inds <- (res$padj<0.01) & (abs(res$log2FoldChange) > 2 )
mycols[ inds ] <- "blue"

plot( res$log2FoldChange, -log(res$padj), col=mycols, xlab="Log2(FoldChange)", ylab="-Log(</pre>

Q6. Finally for this section let's reorder these results by adjusted p-value and save them to a CSV file in your current project directory.

Save results

```
res = res[order(res$pvalue),]
write.csv(res, file ="deseq_results.csv")
```

Pathway Analysis

Use the gage package for pathway analysis and the pathview package to draw pathway diagrams

```
library(pathview)
library(gage)
library(gageData)

Q8: What pathway has the most significant "Entities p-value"? Do the most significant pathways listed match your previous KEGG results? What factors could cause differences between the two methods?

Cell cycle, mitotic has the most significant "Entities p-value). The most significant pathways listed do not match my previous KEGG results for both up and down regulated genes. The only pathway matched is cell cycle for down regulated pathway. The differences between the two methods could be due to the different databases they are drawing information from.
